## Outline

- **The Query Optimizer**
  - Overview
  - Detailed architecture and behaviors
  - Strengths and weaknesses
  - Designing and coding for best results
- **Execution Plan Analysis**
  - Execution engine architecture
  - Basic plan analysis
  - Query plan operators and properties
  - Advanced plan analysis
    - Common patterns
    - Changing data

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

**Mastering Execution Plan Analysis**

**The SQL Server Query Optimizer**

## Concepts

### SQL

- Origins in set theory & relational algebra
- Bags not sets and other quirks
- Declarative not procedural
- Binding order

### Execution Engines

- Row mode: a demand-driven pipeline of iterators
- Batch mode execution available from SQL Server 2012
- In-memory OLTP engine from SQL Server 2014

### Query Optimizer

- The bridge between SQL and the execution engines
- Same logical results but greater efficiency
- Different goals than optimizing compilers in other languages

FROM  
ON  
JOIN  
WHERE  
GROUP BY  
CUBE / ROLLUP  
HAVING  
SELECT  
DISTINCT  
ORDER BY  
TOP

## SQL Server Architecture

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Query Optimization Pipeline

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Parse & Algebrize

- **Parse**
  - Check syntax and semantics
  - Covert to a “parse tree” of logical operations
  - Identify constants for server-side parameterization
- **Algebrize**
  - Name resolution
  - Bind object references to metadata
  - Derive expression types
  - Bind aggregates to grouping expressions
  - Constant folding
  - Parameter embedding
  - Output is a bound tree of logical operators
  - Bound trees may be cached for e.g. views, constraints, and defaults

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Constant Folding & Parameter Embedding

- **Constant folding**
  - Early evaluation of constant expressions to improve performance
  - Arithmetic & logical expressions
  - Some *deterministic* built-in functions
  - Additional cases for cardinality estimation only
- **Parameter embedding**
  - Requires OPTION (RECOMPILE)
  - Not WITH RECOMPILE
  - From SQL Server 2008 SP1 CU5 (build 10.00.2746) onward
  - Parameter values and some T-SQL expressions fully evaluated
  - Significant tree rewrites are possible
  - Occurs before cost-based optimization
  - Not applied when assigning to a variable; other minor exceptions

<http://www.SQLIntersection.com>

## Demo

### Demo Q1

Constant Folding & Parameter Embedding

**Demo**

Demo Q2  
Bound Logical Tree

**SQL intersection**

## The Simplification Phase

- **Predicate & projection pushdown**
  - Eliminate rows and columns as early as possible
  - Index & computed column matching
  - Automatic statistics generation
- **Rewrite logical subqueries**
  - As inner join
  - As outer join (with group by and projection as necessary)
  - As an apply
- **Simplify joins**
  - Full and outer join to inner join
  - Remove redundancies
- **Remove empty expressions**
- **Originally aimed at generated T-SQL**
  - All or nothing & performed only once

18

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo Q3

The Simplification Phase

## Cardinality Estimation

- **Estimate the size of intermediate & final results**
- **Inputs**
  - Base relation cardinality information
  - Statistics histograms & density
  - Trie trees for short strings
- **Derived statistics**
  - Histogram & density recomputed after each logical operation
  - New alternatives may generate new operations
  - No general guarantee of consistency
  - Many modelling assumptions
- **Cardinality estimates influence initial join order heuristics**
  - In all but the simplest of cases

15

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## CE Modelling Assumptions

- **Uniformity**
  - Distinct values have equal frequency
  - Values are distributed evenly
- **Independence**
  - Column values are considered to be independent
  - Unless correlation information is available
  - Very limited multi-column statistical support
- **Inclusion**
  - Comparisons always yield a match
  - Users look for data because it exists
- **Containment**
  - The smaller number of distinct values all exist in the larger set
  - Base containment – only applies to base tables

16

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## CE Model Support

- **Specific model support for:**
  - Filter
  - Joins
  - Apply
  - Project
  - Group By
  - Union
  - Top
- **For best results**
  - Use simpler relational constructions
  - Avoid complex expressions and opaque operations
- **Not everything can be modelled**
- **Not everything that could be modelled has been**

17

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## SQL Server 2014 CE

- **New cardinality estimation module**
  - Determined by *context database* compatibility level
  - Trace flag 2312 new CE override
  - Trace flag 9481 original CE override
- **Major features**
  - Main goals are simplicity, consistency, and supportability
  - Groundwork for possible future improvements
  - Exponential backoff
  - Ascending key and general out-of-histogram logic
- **Expectations**
  - Likely overall improvement for most workloads
  - Regressions *will* occur
  - Real testing is required

18

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Some Useful CE Trace Flags

- **Original CE**

- 2301 Enable advanced modelling extensions
- 2389 & 2390 The ascending key problem
- 4137 Minimum selectivity (for conjunctive predicates only)
- 4138 Disable row goals
- 4139 Apply ascending key logic even when stationary

- **New CE**

- 9471 Minimum selectivity for conjunctive *and* disjunctive predicates
- 9472 Independence instead of exponential backoff
- 2363 Debug output
- Many other undocumented model variations in the 94xx range
- Only *documented* flags are supported for production use

19

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo Q4  
Cardinality Estimation

## The Trivial Plan Stage

- **For queries with no cost-based choices**
  - A fast path to avoid the overhead of cost-based optimization
  - Details change over time
  - Occasionally chosen even if plan choices exist
- **Things that may prevent a trivial plan**
  - Subqueries and joins
  - Some query hints
  - Cost threshold for parallelism
- **If a trivial plan is chosen:**
  - Simple parameterization evaluated for safety
  - Query optimization may end here

27

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo Q5  
The Trivial Plan Stage

## The Cost-Based Optimizer

- **Uses the Cascades framework**
  - Many public research papers
- **Initialization**
  - Copy logical tree nodes into a “memo” structure
  - Initially one memo group per tree node
- **Operation**
  - Explore logical alternatives
  - Implement using physical operations
  - Calculate expected costs
  - Rinse & repeat
  - Choose the cheapest combination
- **Goals**
  - Find a reasonable plan quickly
  - Not an exhaustive search

28

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo Q6

Cost-Based Optimizer Input

## Memo Groups

- **Logical properties**
  - Input & output column list
  - Data types and nullability
  - Keys & functional dependencies
  - Column value ranges
  - *Constant per memo group*
- **Physical properties**
  - Sort order
  - Cardinality estimate
  - Parallelism
  - Execution mode
  - Halloween protection
  - *Vary per memo group*

25

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Four Types of Optimizer Rules

- **Simplification**
- **Exploration**
  - Generate new logical alternatives
  - For a single group or a subtree
  - Mostly relatively simple operations
  - Explorations may combine to produce more complex effects
- **Implementation**
  - Physical implementation of a logical operation
  - Generate estimated operator cost
- **Enforcers**
  - Required sort orders
  - Execution modes
- **395 rules in SQL Server 2014**

26

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

### Exploration Rule Example 1

- Inner Join Switch

### Exploration Rule Example 2

- Push Aggregate Below Join (GbAggBeforeJoin)

## Implementation Rules

- Logical to physical

## Disabling Rules

- Join hints
  - LOOP
  - HASH
  - MERGE
- Query hints
  - HASH | ORDER GROUP
  - CONCAT | HASH | MERGE UNION
  - FORCE ORDER
- Undocumented
  - DBCC RULEON | RULEOFF | SHOWRULES
  - OPTION (QUERYRULEOFF)

Demo

Demo Q7  
Optimizer Rules

## Cost-Based Optimization Phases

- **Search 0 – Transaction Processing**
  - Minimum of 3 table references
  - Primarily indexed nested loops join
  - Limited set of exploration rules available
- **Search 1 – Quick Plan**
  - More explorations available
  - May be run a second time with parallelism required
- **Search 2 – Full Optimization**
  - Most comprehensive search
  - Minimum of 5 table references
  - Serial or parallel as decided in search 1
  - Entered directly when USE PLAN hint specified

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Operator Costing

- **Inputs**
  - Cardinality & distribution information
  - Sequential & random I/O
  - CPU worker time
  - Memory
  - Parallelism
- **Many Model Assumptions**
  - Cold cache
  - Indexed nested loops inner side seeks randomly distributed
  - Largely independent of available hardware
- **The Numbers**
  - Little relation to modern realities
  - Estimated cost and batch cost percentage

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Plan Freezing

- **Plan Guides**
  - May not reduce compilation time
  - XML is verbose and expensive to parse
  - Plan shape guides the search space
  - Replaces cost-based pruning & discarding heuristics
  - May time out
  - Expressions not considered
  - Filter position cannot be forced
  - Always runs search 2

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

### Demo Q8

The Memo and Optimization Phases

## For Best Results...

- *Be simple, clear, and relational*
- Be explicit about types
- Define and enforce constraints
- Create filtered, multi-column, and computed statistics as necessary
- Keep statistics up to date
- Think like the optimizer but also consider the whole plan
- Use your knowledge of the data and business process
- Remember new features often have limited optimizer support
- Avoid deep trees where cardinality estimates degrade quickly
- Consider intermediate materialization
- Use hints if necessary, and review regularly
- Learn about the execution engine...

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

### Introduction

- **Reading Execution Plans – The Basics**
  - Scans & lookups
  - Thick lines
  - Actual versus estimated cardinality
  - Expensive queries in the batch
  - Expensive operators in the plan
- **Execution Plan Analysis – Advanced Query Tuning**
  - Requires deeper knowledge of:
    - The execution engine
    - Execution plan operator behaviours and properties
    - Desirable & undesirable query plan shapes

SQLintersection

© SQLintersection. All rights reserved.  
<http://www.SQLintersection.com>

## The Query Execution Engine

- Operates on plans produced by the Query Optimizer
- Stores and retrieves data via the Storage Engine
- SQL-OS provides memory and threading services

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Query Execution Overview

- **Compile if necessary**
- **Retrieve from plan cache**
- **Acquire memory grant**
- **Fix degree of parallelism**
- **Initialize execution**
- **Open plan iterators**
- **Iterative execution**
  - New modes 2012+

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Execution Plan Architecture

- **QO produces one cached plan (CP) per batch**
  - May contain many compiled statements (CStmts)
  - An execution context (MXC) is generated from the CP
  - CStmts converted to executable statements (XStmts) within the MXC
- **The MXC contains runtime information**
  - Parameter & local variable values
  - IDs of objects created at runtime
  - State information (e.g. currently executing XStmt)
  - Expression bindings
  - And much more
- **The MXC is referred to internally as the “execution plan”**

11

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## The Internal Execution Plan

- **The MXC is not the same “execution plan” users see**
  - XML show plan is derived from the MXC
  - Not all iterators are incorporated in the XML
  - Not all internal details are exposed
  - Graphical plans are another abstraction on top

12

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Iterative Execution

- **Execution Plan**
  - A demand-driven pipeline of generic iterators
- **Generic iterators**
  - Perform a single physical data operation
  - Common interface of Open, Get Row, and Close methods
  - Combined into trees we call execution plans
- **Demand-driven**
  - Execution begins at the extreme left
  - Consumers drive producers to do work
  - Data moves from right to left as a result
  - Execution plans suck
- **Pipeline**
  - Iterators *consume* one row at a time

18

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Internal & User Execution Plans Illustrated

### 1 Internal Execution Plan (MXC / XStmt)

<http://www.SQLIntersection.com>

## Demo

### Demo X1

Row mode execution internals

## About Data Access in Execution Plans

- **The optimizer and execution engine try to avoid copying data**
  - Preferred data access is “by reference”
  - Non-leaf plan operators may reference row data directly
  - The storage engine keeps track of the current row
  - Don’t think of complete rows being passed around
  - Some operators necessarily make a copy of the data
  - Details not exposed in show plan output

15

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Reading Execution Plans

- **Right to Left**
  - Useful for a high-level overview
  - Shows *summary* information only
  - Be aware of the underlying mechanisms at work
- **Left to Right**
  - Detailed analysis of critical plans
  - Advanced tuning work
  - The only way to understand certain behaviours
- **Combine both techniques**

17

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

Mastering Execution Plan Analysis

Execution Plan Operators

## Operator Types

- **Pipelined**
  - Consume input & produce output in GetRow() method calls
- **Blocking**
  - Consume entire input in Open() method call
  - Often require a memory grant or other temporary storage
    - Sort
    - Eager hash aggregate and distinct
    - Hash join (build input only)
    - Eager spool, scalar aggregate, UDX
- **Batched**
  - Parallel column store only

19

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Memory Usage

- **All operators require a small amount of memory**
  - State information
  - Runtime calculations
  - This memory is cached with the plan
  - Other *small* memory needs may be allocated on demand
- **Workspace memory grant**
  - Some operations require significant workspace
    - Primarily sorting and hashing
  - Memory grant fixed just before execution begins
  - Split evenly between threads in row-mode parallel plans
  - Exception for index maintenance sorts

20

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Operator Properties

- SSMS tooltips
- Properties window (F4)

| Index Scan (Workclustered)                                                             |                  |
|----------------------------------------------------------------------------------------|------------------|
| Scan on clustered index, entirely on single range                                      |                  |
| Physical Operation                                                                     | Index Scan       |
| Logical Operation                                                                      | Index Scan       |
| Estimated Execution Mode                                                               | Row              |
| Storage                                                                                | Rowstore         |
| Estimated I/O Cost                                                                     | 0.0038657        |
| Estimated Operator Cost                                                                | 0.0045771 (0.4%) |
| Estimated Subtree Cost                                                                 | 0.0045771        |
| Estimated CPU Cost                                                                     | 0.0071144        |
| Estimated Number of Executions                                                         | 1                |
| Estimated Number of Rows                                                               | 514              |
| Estimated Row Size                                                                     | 9.8              |
| Ordered                                                                                | False            |
| Node ID                                                                                | 1                |

| Table    | [TransactionHistory]           |

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Scans and Seeks

- **Scans**
  - May be *ordered* or *unordered*
  - Forward or backward
  - Allocation order scan possible if:
    - Unordered
    - At least 64 pages
    - NOLOCK, TABLOCK or read-only data
  - Not always a full scan
- **Seeks**
  - Singleton seek or seek with range scan
  - Always ordered, may be forward or backward
  - Multiple seeking operations possible

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Key and RID Lookups

- **Not all required columns available in the nonclustered index**
  - Per-row base table lookup using clustering key or heap RID
- **Always implemented using Nested Loops Join**
  - Check operator output columns *and predicates*
- **May be the optimal choice in some cases**
  - Impossible to fully cover every query; or
  - Limited number of lookups to fetch wide data values
- **Can be very slow if random physical I/O is generated**
  - Depending on the storage subsystem
  - Read-ahead adversely affected in any case

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X2  
Scans, Seeks & Lookups

## Filters and Residuals

- **Filter**
  - A predicate that cannot be used to seek an index
  - May have a *start-up expression*
- **Residuals – Hidden Filters**
  - Filter predicates may be pushed into a child iterator
    - Seeks
    - Scans
    - Joins
    - Lookups
  - May have severe performance consequences
  - Often overlooked

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

Demo

Demo X3  
Filters and Residuals

## Nested Loops Join

- **For each outer row, check the inner side for matches**
  - Inner side often correlated
  - Look for “outer references” to confirm
- **Best for:**
  - Small to medium outer input
  - Correlated index seek on inner side
  - May preserve outer side order
  - Very good parallel performance is possible
- **Inner side considerations**
  - Memory grant based on average correlation values
  - Aggregated execution statistics
  - Read-ahead may not be as effective

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Nested Loops Prefetch

- **Outer side key look-ahead**
- **Asynchronous scatter-gather I/O**
- **Ordered or Unordered Prefetch property on join iterator**
- **Also applies to Key and RID Lookups**
- **Join iterator has an extra outer references expression**
- **Prefetch iterator not exposed in show plan XML**

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Probe and Pass Thru Properties

- **Probe**
  - Indicates if an inner side row was found
  - Nested loops and merge join
  - Not shown for merge semi join
- **Pass Thru**
  - Selective inner side execution per row
  - Nested loops join *only*

|                                                                                                                 |                |

## Demo

Demo X4  
Nested Loops Join

## Parallel Plans – Row Mode Execution Model

- Multiple plan branches bounded by exchanges

- Each branch may be serial or parallel
- Each parallel branch contains DOP threads
- Each thread runs in its own execution context (MXC)
- Only MAXDOP threads can be active at the same time

## Inside An Exchange

- Exchanges buffer rows in packets
- Two iterators in one
- Producer side fills packets
- Consumer side reads packets
- CXPACKET waits
  - Consumer: No packet ready
  - Producer: All buffers full

## Exchange Order Preservation

- Exchanges optionally *preserve* sort order
  - Known as a *merging* exchange

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Multiple Parallel Branches

- Parallel merge join plan from the previous demo
- 16-24 threads used at DOP 8
- Multiple independent demand-driven pipelines

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Row Distribution

- **Parallel seek/scan distributes rows across threads on demand**
- **Exchanges also route packets of rows between threads**
  - Strategy identified by the exchange Partitioning Mode:

| PARTITIONING MODE | PACKET DISTRIBUTION                                    |
|-------------------|--------------------------------------------------------|
| Hash              | Hash function on partitioning column values            |
| Round Robin       | Next consumer in sequence                              |
| Broadcast         | Copied to all consumers                                |
| Demand            | Row at a time pulled from the producer                 |
| Range             | Consumers assigned distinct partitioning column ranges |

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Parallel Joins

- **Merge Join**
  - Both inputs hash partitioned on join keys
  - Merging exchanges required
  - Scaling problems as DOP increases
  - Increased parallel deadlock risk
- **Hash Join**
  - Broadcast partitioning if the build input is small
    - Full hash table copy on each thread
    - No probe-side exchange
  - Hash partitioning on join keys otherwise
    - Two non-merging exchanges
    - Hash table split between threads

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Parallel Execution Issues – Row Mode

- Exchanges can be expensive
- Order preservation can reduce efficiency
- Parallel deadlocks are possible
- Plan costing
- TF 8649
- Thread skew
- Parallelism inhibitors
  - Scalar functions, modifying a table variable, system table access...
  - TOP, window functions pre-2012, multi-statement T-SQL functions
  - Backward-ordered seeks & scans
- Inefficient execution model for modern CPU designs

## Batch Mode Parallel Execution

- Enterprise Edition Only
- Column store index access required
- Vector processing optimized for on-chip caches
- Push mode per segment
- Shared lock-free data access removes need for exchanges
- Any thread can process the next available batch
- Limited utility in SQL Server 2012
- Extensive Improvements in SQL Server 2014
  - Updatable
  - More supported operators
  - Mixed mode plans

## Demo

Demo X5  
Parallel Execution

## Merge Join

- **Inputs must be sorted on the join keys**
  - Can be expensive if sorts are needed
- **Equijoin required**
  - Except full outer join (rare)
- **Many-to-many join requires a work table to handle duplicates**
  - Expensive if used
- **Preserves join key order**
- **Stops when *either* input runs out of rows**
- **Parallel merge join disfavoured**
- **Best for medium-sized serial tasks**

## Hash Join

- **Algorithm**
  - Build a hash table on the join keys
  - Probe hash table for matches
  - Apply residual predicates (bucket scan)
  - Requires an equijoin
- **Features**
  - Blocking on the hash table build input
  - Pipelined on the probe input
  - May spill to physical *tempdb* if hash table exceeds memory grant
  - Role reversal possible if a spill occurs
  - Does not preserve order
  - Best for small build input; medium to large probe input

11

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Bitmaps

- **Parallel plans only**
- **Early semi join reduction**
- **Row Mode**
  - Hash join or merge join with blocking iterator
  - Applied to single probe side exchange, scan, seek, or filter
  - INROW optimization for integer and bigint types
- **Batch Mode**
  - Bitmap created at batch hash table build operator in SQL 2012
  - BHTB no longer needed in 2014
  - Bitmap Creator property
  - Can be split and applied in column store scan access method

12

<http://www.SQLIntersection.com>

Demo

Demo X6  
Bitmap Magic

## Aggregates and Distinct

- **Stream Aggregate**
  - Requires input sorted by the GROUP BY columns
  - Preserves that order
- **Hash Aggregate**
  - Blocking
  - Flow Distinct variant is pipelined
  - Preferred for larger sets with fewer groups
- **Distinct Aggregate e.g. COUNT(DISTINCT x)**
  - Implemented as separate grouping and aggregation operators
- **Sort Distinct**

1/1

© SQL Intersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X7  
Aggregates and Distinct

## Top N

- **Any N rows without an ORDER BY clause**
  - Repeatable results require a deterministic ORDER BY
  - *Only* top-level ORDER BY guarantees result set order
- **Specifying a percentage requires reading the full input set**
- **WITH TIES applies to the final group only**
- **Row goal subtree effects**

Demo

Demo X8  
Top and Row Goals

## Constant Scan & Compute Scalar

- **Constant Scan**
  - An in-memory pseudo-table of expressions or constant values
  - May have no columns
- **Compute Scalar**
  - Defines an expression
  - Evaluation is often deferred
  - May be present for internal reasons
  - Often reveals implementation details
  - Not always very tidy

1/1

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Sort

- **Blocking**
- **Spills to physical tempdb if memory grant is exceeded**
- **Can perform a distinct during sorting**
- **Normal algorithm is a variety of mergesort**
  - Separate algorithm for Top N Sort where  $N \leq 100$
  - In-memory standard library *quicksort* for Constant Scan input
- **Memory fractions property**
- **SQL Server 2012 show plan enhancements for:**
  - Spills
  - Detailed memory grant information
  - Memory grant wait time

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X9  
Compute Scalar and Sort

## Segment and Sequence Project

- **Segment**

- Sets a flag for the start of a new group in a sorted stream
- Window functions
- Segment spool
- Segment top

- **Sequence Project**

- Compute Scalar for ordered streams (a sequence)
- Adds a computed column e.g. row\_number

81

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

Demo

Demo X10

Segment and Sequence Project

## Spools

- **A temporary work table backed by *tempdb***
  - May not cause any physical I/O
  - Eager or lazy accumulation of rows
- **Lazy Table Spool**
  - Often seen on the inner side of a nested loops join
  - Work table truncates on rebind
  - Performance spool combines this with an outer side sort
- **Eager Index Spool**
  - Seek predicate identifies the index keys
  - Always built on a single thread

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X11  
Eager Index Spool

## Union

- **Union All**
  - Preserves duplicates
  - Concatenation or Merge Join iterators
- **Union**
  - Removes duplicates
  - Merge or Hash iterator
  - Concatenation with following distinct
- **MERGE / CONCAT UNION hint**
  - Only effective for UNION ALL from SQL Server 2012 onward

85

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Union All Ordering

86

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X12  
Preserving Order

## Assert

- **Verifies a required runtime condition holds**
  - Constraint checking
  - Subqueries that must return one row

## Updates

- **Internally, all changes are known as *updates***
  - INSERT / UPDATE / DELETE / MERGE etc.
- **One of the most complex areas of the Query Processor**
  - Constraint checking
  - Indexed view maintenance
  - OUTPUT clause
  - Composable DML
  - Non-updating updates
  - Transient key violations
  - Halloween protection
  - INSTEAD OF triggers

The slide features the SQLintersection logo in the bottom left corner, which includes a blue square icon with a white 'G' shape and the text 'SQL intersection'. In the bottom right corner, there is small text: '© SQLintersection. All rights reserved. http://www.SQLintersection.com'. A large, faint, light blue 'G' shape is visible in the background on the right side.

## Update Iterator Properties

- **SSMS Object Properties**
  - Expand to see other affected indexes
- **DML Request Sort**
  - When *true*, rows must be presented in index key order
  - Required to enable insert minimal logging in SQL Server 2008+
- **Ordered or Unordered Prefetch**
  - Issues asynchronous reads
  - Reads about-to-be modified index pages into memory in advance

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Halloween Protection

- **Read/write phase separation**
- **Not always an Eager Table Spool**
- **Iterators may combine to provide necessary level of protection**
- **Can explain redundant sorts**
- **Halloween Protection is required for:**
  - UPDATES where index keys are both searched and updated
  - INSERTs where the target table is referenced in the SELECT clause
  - DELETEs with a self-join of the target table in the SELECT clause
  - MERGE similar to separate INSERT/UPDATE/DELETE operations
  - Specific “hole-filling” OLTP optimization for MERGE only

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Per-Index (Wide) Update Plan Shape

- Separate iterator branch for nonclustered index maintenance
- Eager Table Spool for multiple nonclustered indexes
- Sequence iterator processes each index fully in turn
- May sort keys per index to encourage sequential I/O

## Per-Row (Narrow) Update Plan Shape

- Multiple nonclustered indexes maintained by one iterator
- An optimization for smaller change sets
- I/O pattern may be random w.r.t each index
- Not available for all types of update
- Plans may combine per-index and per-row strategies

## Non-Updating Updates

- Plan may be configured to skip *unchanged* nonclustered index rows
  - Compute Scalars determine if a change in value has occurred
  - Filter eliminates any redundant updates
  - Filter not visible in per-row (narrow) plan shape
  - Clustered index changes are *never* skipped
  - Still best to explicitly filter unchanged rows in the query

## Demo

Demo X13  
Changing Data

## Split, Sort, Collapse Pattern

- **Required for unique index maintenance**
  - Prevents transient key violations
  - Storage Engine requires unique indexes to be unique at all times
  - Forces a per-index (wide) update plan for the index concerned
- **Algorithm**
  - Split the update into a delete and an insert
  - Sort by index key and action code
  - Collapse adjacent delete & insert pairs back to a single update

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X14  
Split, Sort, Collapse

## Partitioned Tables

- **APPLY model used in SQL Server 2005**
  - Constant Scan drives a per-partition nested loops join
- **SQL Server 2008+ uses an implied leading index key**
  - Still uses APPLY pattern for collocated join and partitioned index build
  - Except single partition OFFLINE build
  - Index order may be unexpected
  - Static or dynamic partition elimination is possible
  - Look for:
    - RangePartitionNew
    - PtnIdxxxx

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Reverse Engineering an Execution Plan

- **Large plans can cause problems for optimization and execution**
  - Not always obvious how to simplify
  - QO may produce an optimal section as part of a poor plan
- **Often possible to write T-SQL directly from a plan section**
  - Check plan properties carefully
  - May require hints
- **Intermediate materialization**
  - Simpler queries generally optimize better
  - Better information for the optimizer
  - Easier to maintain and spot improvements e.g. useful indexes
  - Use common sense!

© SQLIntersection. All rights reserved.  
<http://www.SQLIntersection.com>

## Demo

Demo X15

Reverse Engineering a Query Plan

## Final Thoughts

### ▪ Common Execution Plan Problems

- Inaccurate estimates
- Bad lookups
- Residual predicates
- Spilling hashes and sorts
- Many to many merge
- Avoidable sorts
- Parallelism issues
- Memory grant too large
- Missing optimizer fixes
- Inefficient whole-plan strategy

### ▪ Plan Explorer Upload
